

CS Senior Design Self Assessment

Michael Rhode

Part A

I contributed mainly to the backend PostgreSQL implementation in our project. Since our service is based on real time data, we needed a place to put people's picks, accounts, leaderboard structure, etc. of which I helped implement. I did build on the skills I identified in fall in that I need to use Postgres using other languages instead of using a standalone environment to run Postgres queries and house the tables.

Over the course of the project, I learned that it gets very difficult to track what is being added to a project and how that affects other parts of the system that you need to add. The main obstacle I found was implementing tables in a way that the other members could easily manipulate via their queries or populate via API calls. My main success was creating a scheme for each table that has everything that we would need for it to function without having any bloat.

Part B

Our group accomplished creating an application that combines multiple sports and esports into a pick-em style bracket where you can create challenges to have friendly competition with friends, family, and anyone else. I learned that group work can be difficult to come to conclusions as to how something should be implemented when there were multiple potential paths to our finished product. Our team meetings were very successful as they helped us keep track of each other and our accomplishments thus far.

I didn't see any aspects of teamwork that stood out as not working. Any time we came to a problem, we would all work together to find a solution even if other members needed to put extra effort in to make it happen. I believe that Luke Myers did especially well since he has helped with both the backend and the frontend, and saved me from some of our internal deadlines.
